Supplementary Fig. 1. Representative case of BioFreedom stent implantation before planned noncardiac surgery. A 74-year-old man diagnosed as having pancreatic cancer (arrows) with biliary stent implantation (A and B) underwent coronary angiography as a preoperative evaluation of the clinical presentation of unstable angina. A coronary angiogram revealed significant stenosis of the left anterior descending artery (C) and right coronary artery (D). BioFreedom stents (3.0×24 mm and 3.0×28 mm) were implanted in the left anterior descending artery (E) and right coronary artery (F) without complications. The patient underwent noncardiac surgery 35 days after revascularization and was discharged on day 42 without any complications.
